About BioPhorum

BioPhorum's mission is to create environments where the global biopharmaceutical and device industry can collaborate and accelerate its rate of progress, for the benefit of all.

Since its inception in 2004, BioPhorum has become the open and trusted environment where senior leaders of the biopharmaceutical industry come together to openly share and discuss the emerging trends and challenges facing their industry.

Growing from an end-user group in 2008, BioPhorum's membership now comprises top leaders and subject matter experts from global biopharmaceutical manufacturers and suppliers, working in both long-established and new Phorums. They articulate the industry's technology roadmap, define the supply partner practices of the future, and develop and adopt best practices in drug substance, fill finish, process development and manufacturing IT.

In each of these Phorums, BioPhorum facilitators bring leaders together to create future visions, mobilize teams of experts on the opportunities, create partnerships that enable change and provide the quickest route to implementation, so that the industry shares, learns and builds the best solutions together.

Abstract

Cell and gene therapy (CGT) represents a novel and growing class of innovative products that often have complex manufacturing processes. In many cases, genetic material is introduced into eukaryotic cells via transient transfection, a critical manufacturing step. Due to inherent complexity and criticality, there is an acute need for a standardized approach for chemical transfection reagents' certifications of analysis (CoAs) used in GMP manufacturing processes.

Herein, a quality by design (QbD) approach was employed to derive manufacturing process- and product-impactful raw material and/or ancillary material attributes. Although polyethyleneimine (PEI), a cationic polymer, is explored as an exemplar chemical transfection reagent, this approach is also applicable to other transfection reagents used in CGT manufacturing processes. The analysis and learnings discussed may be extrapolated to other transfection materials providing a platform for discussion with supplier and ideally enabling uniform and meaningful material attributes to be reported on these CoAs.

Introduction and scope

CGT products are disruptive modalities that were introduced to complement medical solutions offered by small molecules and classical biologics. CGT represents a class of novel and innovative products that has the potential to cure orphan diseases and genetic disorders with limited, or no pre-existing treatments. CGT products often have complex manufacturing processes, some of which involve the transfer of genetic material of eukaryotic cells via a transient transfection.

The transfer of free genetic material into a cell does not occur naturally. Transient transfection requires the presence of particular physical (e.g. membrane disruption through electroporation) or chemical conditions to enable entry of the nucleic acid through the plasma membrane. Cationic polymers and lipid nanoparticles are the preferred classes of transfection reagents in the industry to achieve large-scale transfection for both adherent and suspension cells. The absence of standard practices for the characterization and testing of these transfection reagents raises quality concerns that may hinder product development and increase costs for CGT product developers.

The scope of this stimulus article will focus on the cationic polymer, polyethyleneimine, commonly known as PEI. Using the QbD approach, the target material profile of PEI will be assessed as to its intended use, quality, safety and the regulatory criteria needed to manufacture a cell and gene therapy drug substance (DS), intermediate and/or drug product (DP). A set of material attributes will be defined to understand the performance and predicted outcome of the raw material from both a scientific and risk strategy. The goal of this article is to establish a control strategy for PEI and harmonize information across suppliers and recommend test methods that contribute to robust CGT process manufacturing.

2.0

Regulatory landscape

Table 1 looks at each regulation and highlights how it either supports the CGT specification space or provides challenge.

Table 1: Regulatory landscape review

| Guideline | Focus |
|--|--|
| USP-NF <1043> Ancillary Materials for Cell, Gene and Tissue-Engineered Products | Development of the appropriate material qualification programs for CGT products. |
| ISO 20399 Biotechnology—Ancillary materials present during the production of cellular therapeutic products (2018) | Part 2 is targeted at ancillary material (AM) suppliers on best practice to ensure consistent manufacture of AM products. It describes the information that should be obtained and provided to the AM user to demonstrate lot-to-lot consistency of the AM product with respect to characteristics, quality attributes, biosafety and performance. |
| ICH M7 Assessment and control of DNA reactive (mutagenic) impurities in pharmaceuticals to limit potential carcinogenic risk—Scientific guideline | ICH M7 page 13 gives acceptable daily intake of an unknown DP elemental impurity. Currently there is no impurity limit for polyethyleneimine. |

The following additional points should be considered:

- The USP general chapter <1043> describes different types of AM and risk categories for these. Per USP <1043>, AMs are raw materials that are not intended to be in the final therapeutic product. ISO 20399 is similarly targeted at AMs (defined as materials introduced during the manufacture of cellular therapeutic products) used in CGT manufacture but is further targeted at suppliers on best practice to ensure consistent manufacture of AMs and describes the information that should be obtained and provided to the material user to demonstrate lot-to-lot consistency with respect to characteristics, quality attributes, biosafety and performance.
- From the manufacturer's perspective, USP <1043> would expect product safety including screening, qualifying, documenting sources of animal-derived components as free of suspected adventitious agents, and validating inactivation and testing of initial raw material and final purified human-/ animal-derived components for the presence of such agents. However, there are no definitions of animal-derived component-free levels in USP general chapter <1043>. ISO 20399 describes levels of animal-derived component-free and guides testing approach to demonstrate lot-to-lot consistency with respect to composition, including identity, quantity and purity of components. Testing requirements include microbial and viral contamination, and non-biological contamination. If a claim is made regarding consistency, especially of performance, functional assay should support claims as well as performance testing.

- Relevant to polymer-based transfection reagents, suppliers typically describe the grades of materials used in CGT manufacturing as research use only (RUO) or research grade, good manufacturing practice (GMP) 'grade' or research for further manufacturing use (RMF)
- It is the responsibility of the CGT product manufacturer to qualify a given AM for their application and to ascertain the material's labeling, essential features, quality characteristics and suitability for use. Fundamentally, the user must consider the impact of material quality on product

quality, taking a QbD approach to the development process in accordance with ICH Q8 (R2) and a risk management approach consistent with ICH Q9 (step 4) Quality Risk Management, ICH Q11 (step 4) Development and Manufacture of Drug Substances

- Further consideration from CGT product manufacturers on the final DS and/or DP is to ensure proper clearance of all elemental impurities. In the case of PEI, there is currently no safe limit specified by USP. The ICH M7 guidance defines a conservative acceptable limit for low-risk chemicals that have not yet been studied.

3.0

Material characteristics and test requirements

3.1 Overview of QbD approach

Transfection reagents are a heterogeneous group of complex, non-compendial raw materials that play integral roles in CGT manufacturing (e.g. triple transfection step in lentiviral vectors (LVV) or adeno-associated virus (AAV) production). Due to the complexity, variety and often proprietary nature of these reagents, identifying key material attributes and avenues of controls can be challenging for end-users. Current control strategies often rely on reviewing supplier CoAs.

However, supplier CoAs are inherently DP/DS-agnostic and may not capture the most meaningful material attributes for a specific CGT application. Furthermore, CoAs often vary between suppliers, making the evaluation of transfection reagents across suppliers difficult without additional criteria.

The aims of this paper are two-fold:

1. To build a deeper technical understanding of the material characteristics most critical for transfection performance
2. To better understand how these material attributes fit into the broader control strategy of an example CGT process.

To achieve these goals the *BioPhorum approach to the registration of innovative raw materials using quality by design principles*² was implemented. The original document was developed as a guide for describing complex raw materials based on identified critical material attributes (CMAs). Although the original focus was to enable greater supply chain flexibility (e.g. dual sourcing) and streamline comparability assessments (regulatory submissions), the framework it presents for systematically collecting and integrating material, process and product knowledge is of broader value.

The BioPhorum approach is a four-step process based on QbD principles. These four steps are:

Figure 1: Outline QbD process

The QbD approach is a mature quality approach to the definition of product quality, as described in ICH Q8. The mature quality approach is defined as a control strategy based on the definition of the quality target product profile (QTPP), of the product critical quality attributes

(CQAs), of linking material attributes and process parameters to the DP CQAs.

Sections 3.2 to 3.6 describe how this process was applied to PEI-based transfection reagents used in lentiviral triple transfection.

3.2 Defining the quality target material profile (QTMP) and material attributes

This paper focuses on the cationic polymer, PEI, as the transfection reagent. PEI is available in either powder or liquid form from multiple suppliers. It is important to understand the material profile and attributes to ensure successful use of the material and meet the quality requirements for GMP manufacturing. When working with PEI at manufacturing scale, four groups of attributes need to be addressed by the supplier to ensure that the raw material is suitable for use; those attributes are as follows: physical, chemical, microbial and safety.

Physical attributes of the PEI raw material such as molecular weight, polymer chemistry (degree of branching) and osmolality contribute to the overall function of PEI in regard to the polydispersity and Zeta potential of the raw material.

Chemical attributes of the PEI raw material such as pH, optimal buffers for formulation of the raw material, complexation media and cell culture media also contribute to the polydispersity and Zeta potential of PEI. These chemical attributes allow for binding and

condensing of DNA into small particles that are delivered to the cell membrane. pH and Zeta potential of the raw material directly affect the surface charge of the PEI and how well it will bind and condense DNA, contributing to the size of the final complex. Polydispersity of the raw material and the final complex will dictate the transfection efficiency or how well the particles transfect the majority of the cells. Due to the nature of PEI used for CGT, the raw material should have minimal cytotoxicity with an understanding of the molecular weight along with any degree of side branching.

The microbial and safety attributes of the PEI raw material are maintained by manufacturing in accordance with current good manufacturing practice (cGMP) guidelines under robust quality systems (e.g. ISO, ICH7) to ensure requirements are met under EMA/USP/ICH. A supplier process validation package containing the minimum safety information as follows: sterility or low bioburden (powder form), animal origin-free (AOF) manufacturing, a supplier stability study (ideally with 24 months of data) and current manufacturing facility in accordance with harmonized GMP requirements for ATMPs from USP 1043, ICH Q11 and EudraLex Volume 4 Part IV.

Table 2: Quality target material profile (QTMP) and material attributes

| Quality target material profile (QTMP) | | | | Intended use | | Quality criteria | | Safety criteria | | Material attributes | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

| | | | Physical attributes | | | | | | | | Chemical attributes | | | | Microbial attributes | | Other safety attributes | | | | Built into process design and overall manufacturing capability | | |
| | | | Appearance | Molecular weight | Polymer chemistry—structural modifications | Polymer chemistry—degree of branching | Osmolality | pH | Buffer additives/reagent formulation | Identity assay | Polydispersity | Complexation media components | Cell culture media components | Elemental impurities | Monomer content and polymerizing agents | Reagent surface charge density (Zeta potential at a given pH and temp) | Sterility or low bioburden for powder products | Low endotoxin | Mycoplasma free | Animal-origin free manufacturing | Supplier stability study minimum 24 months | Manufacturing facility in accordance with USP <1043> or equivalent such as ICH Q11, Eurdrex Volume 4 Part IV: GMP requirements for ATMPs | Supplier process validation package |
| Quality target material profile (QTMP) | Safety criteria | The reagent should be animal-origin free with an animal-derived component free certificate or Bovine Spongiform Encephalopathy (BSE) Transmissible Spongiform Encephalopathy (TSE) statements | | | | | | | | | | | | | | | | | ✓ | | | | |
| | | Clearance of transfection reagent | | | | | | | | | | ✓ | ✓ | | | | | | | | | | As part of process characterization understand impurities limits in drug products |
| | | The reagent should have nitrosamine, halal, melamine statements | | | | | | | | | | | | | | | | | | | | | |
| | | If bought in a powder format, it would be expected to have a low bioburden if in semi-finished state, i.e. liquid format sterility assurance required by notified body | | | | | | | | | | | | | ✓ | ✓ | ✓ | | | | | | |
| | Manufacturability—other requirement | The reagent should perform well at small- and large-scale processes—scalability | | | | | | | | | | | | | | | | | | | | | Note physical and chemical attributes need to remain consistent regardless of volume Process characterisation study |
| | | The reagent should have demonstrated stability over proposed shelf life. Shelf life based on understanding of stability-indicating attributes (proposed checked off). Minimum shelf life of 24 months | | ✓ | ✓ | ✓ | | | | ✓ | ✓ | | | | | ✓ | ✓ | ✓ | | ✓ | | ✓ | Requirement= stability study (supplier or internal) |
| | | The reagent must have a defined process- and product-related impurity profile or documented risk assessment | | | | | | | | | | | ✓ | ✓ | | | | | | | | ✓ | |
| | | Compatibility with other process components | | | | | | | | | | | | | | | | | | | | | As part of supplier selection and process validation |
| | | Stability of the intermediate, i.e. transfection reagent and plasmid in unique process environment | | | | | | | | | | | | | | | | | | | | | Process characterisation study |
| Pack size and configuration should be carpetable with current and future state of the process | | | | | | | | | | | | | | | | | | | | | | As part of the supplier selection and process characterisation studies | |

3.3 Defining the product control strategy

The product control strategy is based on process and product understanding. The product control strategy assures process performance and product quality by using a planned set of controls. The PEI control strategy defines the risks associated with the current CGT process steps and the product quality or CQAs that are directly impacted by PEI. Twelve CQAs have been defined against seven CGT process steps and the control measures that influence the CQA at the intermediate, purified DS and/or final DP stage.

Table 3 shows the product control strategy for PEI. The green boxes across the top represent each step in a CGT process. The yellow/orange boxes represent the CQA or release specification test for an intermediate, purified DS or a final DP. The 'green checkmarks' represent the process step(s) that affect the CQA. The writing underneath the 'green checkmark' details the steps involved and potential control measures to take. The 'red boxed X' represent the process step(s) that do not affect the CQA.

Table 3: Product control strategy or process

| Preculture and expansion | Bioreactor production— Transfection complex prep | Bioreactor production— Add transfection complexes onto the cells in the BRX | Bioreactor production— Incubate cells with transfection complexes | Bioreactor production— Harvest and clarification | Downstream purification and formulation | Final fill finish | CQA: Release spec test for end product/ intermediate Purified DS |

3.4 Defining the critical material attributes (CMAs)

A systematic risk assessment approach was used to define CMAs and respective control strategies for the material attributes of PEI-based transfection reagents (defined in Section 3.2). While both the solid PEI and solution preparations are discussed, the attributes were evaluated based on the liquid formulation of the reagent. Adequate steps must be taken to solubilize the solid PEI material prior to transfection steps. Although both solution and solid material are discussed interchangeably in this document, additional evaluation of material attributes and control strategy may be necessary for the solid form.

Scoring was performed in three categories: (1) **Impact** on product quality and process performance, as outlined in the QTMP and product control strategy, (2) **supplier variability** and (3) **detection**. The results of the scoring,

the rationale for each score and the respective control strategies are summarized in Table 4.

CMAs are defined as attributes that have a high impact on product quality or process performance. To ensure the desired quality of the output material, controls such as appropriate limits, ranges or distributions must be defined for these material attributes.

While medium-impact attributes are not considered critical, they still require control as they may affect product quality and process performance when combined with other attributes. The necessity of controls for these attributes is determined by scoring of the variability and detection.

The scores in each category were defined according to the BioPhorum approach² [BioPhorum's QbD approach to registering complex raw materials as guidance](#). Tables can be found in Appendix 1.

Table 4: Definition of critical material attributes

| Physical attributes | | | |
|--|--|--------------------|---------------|
| Appearance | | | |
| Impact—Medium | | Variability—Medium | Detection—Low |
| Rationale | <ul style="list-style-type: none">Impact is scored as medium: appearance of material can be visually inspected to identify any issues; the impact of these issues could varyVariability is scored as medium: appearance may be dependent on the manufacturing process or the chemical composition of the transfection reagent, which may vary between suppliersDetection is scored as low: appearance is included in the incoming raw material testing; testing for the degree of coloration and for particulates should also be included in the CoA. | | |
| Control strategy | Include degree of coloration and particulates in the CoA. Include appearance of the transfection reagent in the incoming raw material testing. | | |
| Molecular weight (MW) | | | |
| Impact—High | | Variability—High | Detection—Low |
| Rationale | <ul style="list-style-type: none">Impact is scored as high: MW of PEI-based transfection reagents impacts their performance and cytotoxicityVariability is scored as high: MW may depend on the product and distinguish one product from anotherDetection is scored as low: well-defined methods to determine MW, such as gel permeation chromatography (GPC), are in place. | | |
| Control strategy | MW should be included in the CoA. | | |
| Polymer chemistry—structural modifications | | | |
| Impact—High | | Variability—High | Detection—Low |
| Rationale | <ul style="list-style-type: none">Impact is scored as high: structural modifications could change the surface charge of the polymer and affect the performance of the transfection reagent, i.e. the transfection efficiencyVariability is scored as high: structural modifications of the PEI distinguish one product from anotherDetection is scored as low: intended structural modifications should be easy to detect with an in-house test panel specified by the end-user. It should also be included in the CoA. Unintentional structural modifications may be much harder to detect. | | |
| Control strategy | Structural modifications should be included in the CoA. Additionally, an in-house test panel may be set up to test for structural modifications. | | |

Table 4: Definition of critical material attributes (continued)

| Physical attributes | | |
|---------------------------------------|---|------------------|
| Polymer chemistry—degree of branching | | |
| Impact—High | Variability—High | Detection—Low |
| Rationale | <ul style="list-style-type: none">Impact is scored as high: the degree of branching could change the surface charge of the polymer and affect the performance of the transfection reagent, i.e. the transfection efficiencyVariability is scored as high: the degree of branching distinguishes one product from anotherDetecting is scored as low: the degree of branching should be easy to detect with an in-house test panel specified by the end-user. It should be included in the CoA. | |
| Control strategy | Degree of branching should be included in the CoA. Additionally, an in-house test panel may be set up to test for the degree of branching of the polymer. | |
| Osmolality | | |
| Impact—High | Variability—High | Detection—Low |
| Rationale | <ul style="list-style-type: none">Impact is scored as high: the osmolality indirectly impacts the concentration of the PEI-based transfection reagentVariability is scored as high: the reagent concentration may vary between suppliers and so does the osmolalityDetection is scored as low: the osmolality can be easily determined by freezing-point depression. Additionally, the osmolality should be included in the CoA. | |
| Control strategy | Osmolality should be included in the CoA. The proposed analysis method is freezing-point depression. | |
| Chemical attributes | | |
| pH | | |
| Impact—Medium | Variability—High | Detection—Medium |
| Rationale | <ul style="list-style-type: none">Impact is scored as medium: the pH of a PEI-based transfection reagent does not necessarily indicate the reagent's performance but is rather indicative of its composition. Furthermore, the pH might affect the reagent's stability. It also contributes to the pH of the transfection complex solution, which is an important parameter in the transfection unit operation and can affect process performance. The pH of the transfection complex solution can also be modulated by other factors such as supplements. Eventually, the pH of the transfection reagent might affect the pH inside the production bioreactor, which is an important process parameter that can affect process performance. However, the pH inside the bioreactor is measured and can be controlled. Furthermore, the amount of transfection reagent in the production bioreactor is relatively smallVariability is scored as high: the transfection reagent pH values vary between products. Additionally, some of the suppliers have very wide pH specification ranges or do not include the pH in the product specificationDetection is scored as medium: the pH of the transfection reagents can be measured easily. However, pH measurement is not commonly performed in-house and should be provided in the CoA. | |
| Control strategy | pH should be included in the CoA with narrow specification ranges. For the transfection reagent a pH below 6.0 is recommended. In the production process, the pH of the complexation solution should be between pH 7.0 and 9.5 ¹ RESEARCH ARTICLE Unusual Salt and pH Induced Changes in Polyethyleneimine Solutions. | |
| Buffer additives/reagent formulation | | |
| Impact—High | Variability—High | Detection—High |
| Rationale | <ul style="list-style-type: none">Impact is scored as high: certain substances can enhance or impede the performance of PEI-based transfection reagentsVariability is scored as high: there is a lack of knowledge on the buffer formulationDetection is scored as high: buffer formulation and additive specifications are not included in the CoA. Analysis of the transfection reagent formulation is not usually performed by the end-user. | |
| Control strategy | <50mM NaCl (support information: RESEARCH ARTICLE Unusual Salt and pH Induced Changes in Polyethyleneimine Solutions) ¹ . Reagent formulation is analyzed by the supplier and included in the CoA. In-house testing could be performed (e.g. ICP, MS, OES, IC, titration, etc.) | |
| Identity assay | | |
| Impact—High | Variability—High | Detection—Low |
| Rationale | <ul style="list-style-type: none">Impact is scored as high: the reagent's identity determines its performance, i.e. the reagent's ability to transfer DNA into the cellVariability is scored as high: the identity of the transfection reagent is supplier IP and can vary between suppliersDetection is scored as low: the identity assay is part of the supplier release specification and partially included in the CoA. | |
| Control strategy | ID testing is part of the CoA. Methods could include HPLC, NMR, FT-IR, SEC. | |

Table 4: Definition of critical material attributes (continued)

| Polydispersity | | |
|---|---|----------------|
| Impact—High | Variability—High | Detection—High |
| Rationale | <ul style="list-style-type: none">Impact is scored as high: intra-lot variability in the transfection reagent's polydispersity may impact complex formation and contribute to lot-to-lot variability in virus productions. Additionally, the introduction of PEI molecules of various sizes and/or molecular weights into cells may result in unpredictable cytotoxicity. Eventually, polydispersity may be a stability-indicating attributeVariability is scored as high: there is a lack of knowledgeDetection is scored as high: polydispersity may be measured and sufficiently controlled at the supplier but is not included in the CoA. In-house measurements are not usually performed. | |
| Control strategy | Include polydispersity of the reagent in CoA. Methods could include DLS, GPC-RI. | |
| Complexation media components | | |
| Impact—High | Variability—High | Detection—High |
| Rationale | <ul style="list-style-type: none">Impact is scored as high: certain media components may enhance or impede the performance of PEI-based transfection reagents and media vendor proprietary recipes do not disclose specific additives in the media formulationVariability is scored as high: there is a lack of knowledge from supplier to supplierDetection is scored as high: the complexation media may comprise a broad range of components that may interact with the reagent. | |
| Control strategy | Supplier to provide list of components that may interfere with PEI-based transfection. User should perform design of experiment studies to understand the impact to the process. | |
| Cell culture media components | | |
| Impact—High | Variability—High | Detection—High |
| Rationale | <ul style="list-style-type: none">Impact is scored as high: certain media components may enhance or impede the performance of PEI-based transfection reagents and media vendor proprietary recipes do not disclose specific additives in the media formulationVariability is scored as high: there is a lack of knowledgeDetection is scored as high: the complexation media may comprise a broad range of components that may interact with the reagent. | |
| Control strategy | Supplier to provide list of components that may interfere with PEI-based transfection. User should perform design of experiment studies to understand the impact to the process. | |
| Elemental impurities | | |
| Impact—High | Variability—Medium | Detection—High |
| Rationale | <ul style="list-style-type: none">Impact is scored as high: elemental impurities could impact the transfection efficiency and cell culture performance. Both may impact process performance and may result in lot-to-lot variabilityVariability is scored as medium: inter-lot variability of elemental impurities is low. However, changes between suppliers can varyDetection is scored as high: there is a lack of knowledge. It is currently not clear whether elemental impurities are sufficiently reported in the CoA and which elemental impurity profile is acceptable and does not interfere with process performance. | |
| Control strategy | The reagent must have a defined process and product-related impurity profile or documented risk assessment. Elemental impurities should be considered in transfection reagent specification and be included in the CoA. The recommended analytical method is ICP-MS. | |
| Monomer content and polymerizing agents | | |
| Impact—High | Variability—Low | Detection—Low |
| Rationale | <ul style="list-style-type: none">Impact is scored as high: other species like leftover monomers or polymerizing agents included in the transfection reagent may impact the performance of the transfection reagentVariability is scored as low, as testing for monomers or polymerizing agents is part of the suppliers' product purity testing and results are included in the CoADetection is scored as low, as the monomer content and the concentration of polymerizing agents are included in the CoA. Based on the specifications and proposed test method provided by the supplier, monomer content and polymerizing agents could also be measured in-house. | |
| Control strategy | Monomer content and polymerizing agents should be included in the suppliers' product purity testing. Specification should be zero or at a level that is known to not affect transfection efficiency. | |

Table 4: Definition of critical material attributes (continued)

| Reagent surface charge density (Zeta potential at a given pH and temp) | | |
|--|---|----------------|
| Impact—High | Variability—High | Detection—High |
| Rationale | <ul style="list-style-type: none">Impact is scored as high: the surface charge density of a PEI-based transfection reagent influences the electrostatic interactions between the transfection reagent and DNA. Therefore, heterogeneity in the surface charge density may impact the performance of the transfection reagent at multiple steps of the transfection process, including complex formation and intracellular DNA releaseThe variability is scored as high: there is a lack of knowledge. The surface charge density emerges from structural features of the PEI molecule (e.g. polymer length, functional groups, side chains, modifications), which may be supplier intellectual property (IP) and therefore may vary between suppliersDetection is scored as high: the reagent surface charge density must be measured and sufficiently understood and controlled by the end-user. | |
| Control strategy | Engage with suppliers to understand how surface charge is controlled and measured in the manufacturing process. User should perform design of experiment studies to understand the impact to the process. | |
| Microbial attributes | | |
| Sterility or low bioburden for powder products | | |
| Impact—High | Variability—Low | Detection—Low |
| Rationale | <ul style="list-style-type: none">Impact is scored as high: microbial growth will have an impact on the cell culture processVariability is scored as low: process steps for manufacture are validatedDetection is scored as low: sterility testing/bioburden testing is included in the CoA and performed in-house within incoming raw material testing. | |
| Control strategy | Sterility or bioburden testing should be included in the CoA. Sterility testing should be performed in accordance with USP <71> or an alternative recognized test method. Bioburden testing should be performed in accordance with USP <61> / USP <62> or an alternative recognized test method. | |
| Low endotoxin | | |
| Impact—High | Variability—Low | Detection—Low |
| Rationale | <ul style="list-style-type: none">Impact is scored as high: the level of endotoxin will have an impact on the cell culture processVariability is scored as low: process steps for manufacture are validatedDetection is scored as low: endotoxin testing is included in the CoA and performed in-house within the incoming raw material testing. | |
| Control strategy | Endotoxin testing should be performed in accordance with USP <85> or an alternative recognized test method and be included in the CoA. | |
| Mycoplasma free | | |
| Impact—High | Variability—Low | Detection—Low |
| Rationale | <ul style="list-style-type: none">Impact is scored as high: the presence of mycoplasma will have an impact on the cell culture processVariability is scored as low: process steps for manufacture are validatedDetection is scored as low: mycoplasma testing is included in the CoA and performed in-house within the incoming raw material testing. | |
| Control strategy | Mycoplasma testing should be performed in accordance with USP <63> or an alternative recognized test method and be included in the CoA. | |
| Other safety attributes | | |
| Animal-origin free manufacturing | | |
| Impact—Medium | Variability—Low | Detection—Low |
| Rationale | <ul style="list-style-type: none">Impact is scored as medium: AOF transfection reagents are preferred, as animal-derived components might induce inter-lot variabilities and require BSE/TSE statements to ensure product safety. For AOF transfection reagents, an AOF manufacturing process must be ensured, as the unintentional presence of animal-derived components poses a high safety risk. Animal-derived components could be detected in the transfection reagent but are not routinely tested for in-house controls by the end-userVariability is scored as low: PEI-based transfection reagents are synthetically manufacturedDetection is scored as low: the presence of animal-derived components can be identified through CoA and other related supplier documentation. | |
| Control strategy | Animal origin/BSE/TSE statement by supplier, confirming the non-animal origin of all materials used in the manufacturing process. | |

Table 4: Definition of critical material attributes (continued)

| Supplier stability study minimum 24 months | | | |
|---|--|--------------------|------------------|
| Impact—Medium | | Variability—Low | Detection—Low |
| Rationale | <ul style="list-style-type: none">Impact is scored as medium: may have an impact on the performance of the transfection reagent if the material is out of specification. For the supplier stability study a minimum of 24 months is requestedVariability is scored as low: the material is stable in natureDetection is scored as low: the material is supplied with a CoA confirming the product shelf life. | | |
| Control strategy | Expiration date is included in the CoA and supported by the supplier stability study. | | |
| Manufacturing facility in accordance with ICH Q11, EudraLex Volume 4 Part IV: GMP requirements for ATMPs, or equivalent. USP <1043> | | | |
| Impact—High | | Variability—Medium | Detection—Medium |
| Rationale | <ul style="list-style-type: none">Impact is scored as high: the guidelines ensure that the manufacturing facility is designed and operated in a manner that ensures consistent quality and meets the requirements of the intended useVariability is scored as medium: the application of the regulatory guidelines can vary between suppliers. Therefore, a supplier audit should be included in the supplier selection/qualification processDetection is scored as medium: in the supplier qualification process it will be assured that manufacturing facilities have a certified accreditation. Supplier monitoring and audits should be performed regularly. | | |
| Control strategy | Assure that the material is supplied only by manufacturing facilities with certified accreditation. Supplier monitoring and audits are performed regularly. | | |
| Supplier process validation package | | | |
| Impact—High | | Variability—Medium | Detection—Low |
| Rationale | <ul style="list-style-type: none">Impact is scored as high: you would lose assurance the material is manufactured in a control mannerVariability is scored as medium: validation packages can vary between supplierDetection score is low: the drug master files or equivalent are an established quality process accepted by regulatory agencies. Accreditations or certifications by applicable GMP standards further support a low score. | | |
| Control strategy | Filing validation package with regulatory bodies and supplier qualification. | | |

3.5 Defining the material characteristics and test requirements based on QbD approach

Based on the knowledge acquired through the definition of the QTMP, the product control strategy and the CMAs, specifications were defined for the material attributes with high or medium impact on

product quality and process performance. This included recommended test methods that could be used to harmonize the evaluation of these attributes.

Together with the control strategy defined in Section 3.4, Table 5 summarizes the recommended test methods, and specifications for the high- and medium-impact material attributes of PEI-based transfection reagents.

Table 5: Recommended raw material specification for polymer-based transfection reagents

| | | | Proposed testing requirements | |
|-------------------------|--|---|---|---|
| | | Proposed test method | Proposed acceptance criteria | Control strategy for attribute |
| Physical attributes | Appearance | Degree of coloration and particulates | Clear, colorless solution, free of particulates | Check CoA/part of incoming raw material testing |
| | Molecular weight | Gel permeation chromatography (GPC) | Agreed range with vendor—pass/fail | Ask supplier to include in CoA as part of identity testing/ determine internally via e.g. GPC |
| | Polymer chemistry—structural modifications | IR/NMR | Agreed range with vendor—pass/fail | Ask supplier to include in CoA as part of identity testing/ determine internally via test panel |
| | Polymer chemistry—degree of branching | GPC + IR/NMR | Agreed range with vendor—pass/fail | Ask supplier to include in CoA as part of identity testing/ determine internally via test panel |
| | Osmolality | Freezing-point depression | <50mM NaCl | Ask supplier to include in CoA, incoming raw material check |
| Chemical attributes | pH | pH | Acidic solution of pH<6.0 | Based on the manufacturing process when in buffer solution the pH should be 7–9.5pH |
| | Buffer additives/reagent formulation | ICP, MS, OES, IC, titration | <50mM NaCl | Definition of composition—high level Fingerprint testing annual/quarterly Low salt to promote high interchain repulsion so that PEI will be in a favorable linear state |
| | Identity assay | Assay/ID test, e.g. HPLC, NMR, FT-IR, SEC | Pass | CoA check |
| | Polydispersity | DLS, GPC-RI | Monodispersed | Ask supplier to have on CoA |
| | Elemental impurities | ICP—MS | Drug product profile—pass | The reagent must have a defined process- and product-related impurity profile or documented risk assessment |
| | Monomer content and polymerizing agents | Agree as part of supplier purity testing | Zero or at a level that is known not to affect transfection efficiency | CoA |
| | Reagent surface charge density (Zeta potential at a given pH and temp) | To be agreed with vendor | Agreed range with vendor—pass/fail | Assay as final DS release |
| Microbial attributes | Sterility or low bioburden for powder products | USP <71> or alternative recognized test such as PCR | No growth detected or equivalent (example no PCR signal) | Check CoA/part of incoming raw material testing |
| | Low endotoxin | USP <85> or alternative recognized validated test | ≤0.5EU/mL | Check CoA/part of incoming raw material testing |
| | Mycoplasma free | USP <63> or alternative recognized validated test | None detected | Check CoA/part of incoming raw material testing |
| Other safety attributes | AOF manufacturing | In line with internationally recognized regulatory standard | Material is synthetic; supplier to confirm as part of CoA material has not been contaminated with material of animal origin | Statement on CoA |
| | Supplier stability study minimum 24 months | In line with internationally recognized regulatory standard | Shelf life statement—expiry on CoA | CoA expiration date |

3.6 Manufacturing process consideration

Attributes with high and medium impact on product quality and process performance that are not directly ascribed to the transfection reagent itself, but rather to the transfection reagent manufacturing process, were assessed

comparably to the CMAs of the transfection reagent. Specifications and appropriate test methods and control strategies for these attributes were discussed and defined by the team. The recommended manufacturing process and material qualification controls and specifications are summarized in Table 6.

Table 6: Recommended manufacturing and material qualification controls for polymer-based transfection reagents

| | | Proposed testing requirements | | |
|-------------------------|---|---|--|--|
| | | Proposed test method | Proposed acceptance criteria | Control strategy for attribute |
| Chemical attributes | Polydispersity | DLS | Monodispersed | Ask supplier to have on CoA if sold as a solution. Shelf life |
| | Complexation media components | Supplier qualification | User should perform design of experiment studies in order to understand the impact to the process | Supplier to provide list of components that may interfere with PEI-based transfection User should perform design of experiment studies in order to understand the impact to the process |
| | Cell culture media components | Supplier qualification | User should perform design of experiment studies in order to understand the impact to the process | Supplier to provide list of components that may interfere with PEI-based transfection User should perform design of experiment studies in order to understand the impact to the process |
| | Elemental impurities | ICP—MS | Drug product profile—pass | The reagent must have a defined process- and product-related impurity profile or documented risk assessment |
| | Reagent surface charge density (Zeta potential at a given pH and temp) | To be agreed with vendor | Agreed range with vendor—pass/fail | User should perform design of experiment studies to understand the impact to the process Assay as final DS release |
| Other safety attributes | AOF manufacturing | In line with internationally recognized regulatory standard | Material is synthetic—supplier to confirm as part of CoA material has not been contaminated with material of animal origin | BSE/TSE statement |
| | Supplier stability study minimum 24 months | In line with internationally recognized regulatory standard | Material is synthetic, manufactured and stable in nature. CoA would confirm shelf life | CoA expiration date and supplier stability study to support |
| | Manufacturing facility in accordance with USP <1043> or equivalent such as ICH Q11, EudraLex Volume 4 Part IV: GMP requirements for ATMPs | Supplier qualification | Assuring material is supplied by manufacturing facility with certified accreditation and regular supplier monitoring and audits | Supplier qualification |
| | Supplier process validation package | Supplier qualification | Filing validation packaging with regulatory bodies it is assumed process is stable and manufacturing material of the required quality requirements | Supplier qualification |

4.0

Proposal

The CGT space represents new challenges in manufacturing a treatment that is efficacious while being safe for the patient. Each raw material added to the CGT process needs to be scrutinized in regard to safety, and its planned purpose and use. The introduction of target genetic material via transient transfection is a critical step in CGT manufacturing. The reagents required for transfection have broad market differences in manufacturing quality and attributes tested. This paper highlights critical PEI quality material attributes for a successful CGT transient transfection manufacturing process: physical, chemical, microbial and safety. To remedy the current lack of standardization, the QbD approach was used to determine the target material profile of PEI. The QbD approach enabled better understanding of the material characteristics that are most critical for transfection performance, and better understanding of how these material attributes fit into the broader control strategy of a CGT process.

Table 4 demonstrates that microbial and safety attributes are better understood and characterized for release-testing requirements, whereas physical and chemical attributes are significantly tied to the suppliers' proprietary information and process know how. Four of the five physical attributes and eight of the nine chemical attributes were scored with a high impact and high variability, suggesting, with a scientific rationale, that these are critical for the success of a CGT process. This paper outlines the impact and variability scored high due to a gap in knowledge from the field and or suppliers' proprietary information. Seven of the nine chemical attributes were scored with a high or medium detectable score. There is an opportunity for improvement by

working with the suppliers on standardizing a PEI transfection reagent CoA and/or collaborating on a set of appropriate assays needed for regulatory approval. The cumulation of this work is summarized in Table 7.

Clearly, there is an opportunity for improvement by working with suppliers on standardizing a PEI transfection reagent CoA and collaborating on appropriate assays needed for regulatory approval. While this paper outlines a framework for that standardization, it also demonstrates a practical means to extrapolate to other transfection materials prevalent in the CGT industry. With this, industry can build a deeper technical knowledge of these materials and agree to greater standardization in attributes testing.

Table 7: Summary of material attributes and proposed specification

| Material attributes | | | | | | | | | | | | | | | | | | | | | | |
|--|--|--|---|--|--|---|---|--|--|----------------------------------|--|--|--|---|--|--|---|---|---|---|---|---|
| Physical attributes | | | | | | | | | | | Chemical attributes | | | | | | | Microbial attributes | | | Other safety attributes | |
| Appearance | Molecular weight | Polymer chemistry— structural modifications | Polymer chemistry— degree of branching | Consolubility | pH | Buffer additive/ reagent formulation | Identity assay | Polydispersity | Complexation media components | Cell culture media components | Elemental impurities | Monomer content and polymerizing agents | Reagent surface charge density (Zeta potential at a given pH and temp) | Sterility or low bioburden for powder products | Low endotoxin | Microplasma free | AOF manufacturing | Supplier stability study minimum 24 months | Manufacturing facility in accordance with USP <1043> or equivalent such as CH GMP requirements Part IV, GMP requirements for ATMPs | Supplier process validation package | | |

Feedback and responding to the content of the article

Readers are invited to comment on the specific standards and tests where possible, in addition to the overall proposed approach. Feedback may be provided by completing this [form](#).

Specification testing:

1. What experience do you have of supplier ID methods being unable to discriminate similar molecules in their facility? What have you done to address this?
2. What has your organization developed for testing polymer-based transfection reagent identity?
3. Have you used nuclear magnetic resonance (NMR), fourier transform infrared (FT-IR) or other methods for testing polymer-based transfection reagent identity?
4. If yes, could you share more details of your method?
5. What other testing and/or methodology would you recommend?
6. Do you agree with the testing proposed in Table 5?
7. What release specifications do you use: vendor-specified criteria on CoAs, or user/ process-defined CQAs, or other?
8. What is your experience with polymer-based transfection reagents of other origins?
9. What marketed grades of material are you using in your process?
10. What phase of the approval process are you in?

Regulatory:

11. Are there relevant references other than USP <1043> or ISO 20399 that should be evaluated from a regulatory perspective that may dictate the use of these transfection reagents?
12. Would you be interested in helping to write a pharmacopeia entry for transfection reagents?

The team leveraged multiple discussions and undertook a blinded survey to enable sharing of data and opinions. The final proposals are a combination of thoughts, suggestions and questions. The objective of this paper is to solicit feedback on the proposed universal standards and testing for polymer-based transfection reagents. Table 5 sets out an industry best practice which could be used as a basis for a chapter.

Readers are invited to comment on the specific standards and tests where possible, in addition to the overall proposed approach. Feedback may be provided by completing the following [form](#).

The team recognizes that the proposed approach is a work in progress. It understands that many users are doing some innovative work. This is an opportunity for you to use your voice to inform a standardized approach, a baseline of tests and agreed methods that should be followed for acceptable specification ranges for polymer-based transfection reagents.

6.0

Benefits

An agreed framework for release testing polymer-based transfection reagents has many benefits. It will provide confidence that your actions are aligned with those of your peers. The alignment will bring reliability and consistency to the manufacturing process as everyone is meeting the same standard for a particular material.

It will also mean that manufacturers, suppliers and clients can use the same language and refer to an agreed reference table and testing. Importantly, when you come to file with regulatory authorities, you will have a data pack that covers what they will expect to see and that demonstrates you are managing and controlling that material appropriately.

Nobody has tried to define the polymer-based transfection reagent release testing needed for CGT processes, so the BioPhorum approach is an industry first. With the explosive growth of the CGT industry, the need for these release specifications is loud and clear. What do you think?

Appendix

Risk assessment tables used to define the CMAs

| Definition—Impact | |
|-------------------|--|
| Low | Based on our product and process knowledge and understanding, the attribute does not contribute in itself to the QTMP or the control strategy associated with the raw material and its use. Control of product quality or fulfilling of the QTMP may be achieved in different ways. No more characterization required. |
| Medium | Based on our product and process knowledge and understanding, the attribute may contribute to the QTMP or the control strategy associated with the raw material and its use. This attribute has an impact on product and process quality when combined with others. A material attribute of medium impact may require controls. |
| High | Based on our product and process knowledge and understanding, the attribute contributes directly to the QTMP or the control strategy associated with the raw material and its use. Critical material attribute: “A physical, chemical, biological or microbiological property or characteristic of an input material that should be within an appropriate limit, range, or distribution to ensure the desired quality of output material.” |

| Definition—Variability | |
|------------------------|--|
| Low | Based on our product and process knowledge and understanding, the attribute is robust; it presents low variability. |
| Medium | Based on our product and process knowledge and understanding, the attribute may demonstrate some variability. |
| High | Based on our product and process knowledge and understanding, the attribute cannot be described as robust, it presents a high variability. |

| Definition—Detection | |
|----------------------|--|
| Low | The attribute is adequately measured/Failure of the attribute can be detected before it is added to the manufacturing process. |
| Medium | The attribute is measured; however, some variability may occur undetected/failure of the attribute can be detected before product release. |
| High | The analytical method is not appropriate/Failure of the attribute cannot be detected at product release. |

Glossary

| Term | Definition |
|--------|--|
| AAV | Adeno-associated virus |
| AM | Ancillary material |
| AOF | Animal-origin free |
| BSE | Bovine Spongiform Encephalopathy |
| CGT | Cell and gene therapy |
| CMA | Critical material attribute |
| CoA | Certificate of analysis |
| CQA | Critical quality attribute |
| DLS | Dynamic light scattering |
| DP | Drug product |
| DS | Drug substance |
| EMA | European Medicines Agency |
| FT-IR | Fourier transform infrared |
| GMP | Good manufacturing practice |
| GPC | Gel permeation chromatography |
| HPLC | High-performance liquid chromatography |
| ICP-MS | Inductively coupled plasma mass spectrometry |

| Term | Definition |
|-------|--|
| IP | Intellectual property |
| IR | Infrared |
| ISO | International Organization for Standardization |
| LC-MS | Liquid chromatography–mass spectrometry |
| LVV | Lentiviral vectors |
| MW | Molecular weight |
| NMR | Nuclear magnetic resonance |
| PEI | Polyethyleneimine |
| QbD | Quality by design |
| QTMP | Quality target method profile |
| RMF | For research use or further manufacturing |
| RUO | Research use only |
| SEC | Size exclusion chromatography |
| TMP | Target material profile |
| TSE | Transmissible Spongiform Encephalopathy |
| USP | United States Pharmacopeia |
