1. INTRODUCTION

A proficiency test on the analysis of organic matter, phosphorus, chloride, sulphate and suspended matter in wastewater was conducted on 12 September 2013. The proficiency test was organised by Eurofins Miljø A/S.

The present report contains Eurofins' documentation for the quality of the proficiency test. Results of the proficiency test including data from participating laboratories and statistical analysis of these data were issued in a report to all participants and DANA
K /1/ on 8 October 2013.

2. FEATURES OF THE PROFICIENCY TEST

Participants in the proficiency test were a total of 69 laboratories from Denmark, Sweden and Aaland. A list of participants is shown in Appendix A.

The closing date for submission of results was 30 September 2013. All participants had submitted their results before the dead-line.

2.1 Sample preparation

The parameters covered in the proficiency test are listed in Table 2 as are the abbreviations used in this report.

Four samples were dispatched for the proficiency test. The samples were sample pairs covering the parameters as described in Table 1. The matrix of the samples represented wastewater, in this case synthetic wastewater, effluent. Sample preparation is described in Appendix B.

Table 1 Samples in the proficiency test

Sample name	Parameters
A1-BOD/B1-BOD	BOD5 (w ATU); BOD7 (w ATU)
A1-COD/NVOC /B1-COD/NVOC	COD, NVOC
A2/B2	TP, Cl, SO4
A3/B3	TSS

2.2 Statistical analysis of participants' data

A split-level design was used. The data analysis was performed in accordance with ISO 5725: "Accuracy (trueness and precision) of measurement methods and results" (1994) /2/ and as described in detail in Spiiid (1992) /3/. A short introduction to the statistics and a list of symbols and abbreviations used is given in Eurofins document "Schedule for a proficiency test", which is available at Eurofins' home page /4/.

The statistical model used is based on the assumption that the variances for the two samples in a sample pair are identical. The assumption was tested (F-test, 95% confidence level) and the result was that the two variances may be assumed to be identical for all parameters.

2.3 Assigned and spike value

An overview of the concentrations in the samples (the assigned values) and the difference in concentration between the two samples of a sample pair (spike value) are shown in Table 2 compared to the range of concentrations normally encountered in synthetic wastewater, effluent. The table also gives the expanded uncertainty of the assigned values.

Table 2 Assigned and spike value

Parameter	Abbreviation	Unit	Typical Range	Assigned value	Uncertainty of assigned value	Spike value
Chemical oxygen demand	COD _{Cr}	mg/L O ₂	5 – 75	35.4	0.25	9.9
Biochemical oxygen demand, 5 days	BOD ₅ (w. ATU)	mg/L O ₂	2 – 6	1.6*	0.22*	0.3
Biochemical oxygen demand, 7 days	BOD ₇ (w. ATU)	mg/L O ₂	2 – 6	2.1	0.24	0.3
Non-volatile/total organic carbon	NVOC/TOC	mg/L C	2 – 30	14.0	0.095	3.9
Total phosphorus	TP	mg/L P	0.2 – 2	0.325	0.0021	0.051
Chloride	Cl	mg/L	50 – 700	69.3	0.44	6.8
Sulphate	SO ₄	mg/L	20 – 200	29.0	0.18	3.8
Total suspended solids	TSS	mg/L	20 - 100	29.9	0.23	6.0

*: indicative value

2.3.1 Assigned and spike values

The content of each parameter in each sample is given an assigned value for the sample with the lower content and a spike value, the spike value being the difference in concentration between the two samples of the sample pair. The assigned and spike values are both calculated from sample preparation except for BOD where spike values are calculated from sample preparation and assigned values are consensus values for laboratories using standardised methods (method no. 1 - 4), based on the median.

Only four laboratories used standardised methods for BOD₅ (w ATU). Therefore the value indicated in Table 2 is indicative only.

2.3.2 Test of spike values

A comparison was made (t-test, 95% confidence level) between the spike value and the difference in concentration between the two samples in the sample pair found from the laboratories' results, see Appendix C. The test showed no significant difference between the two. The test revealed a significant difference between the two for TP. However, the difference is numerically small (0.002 mg/L P) and has insignificant influence on the general quality of analyses estimated from the data as well as on the evaluation of accuracy of participating laboratories.

2.3.3 Test of assigned values

The assigned value and the average of the results obtained from all laboratories were also compared (t-test, 95% confidence level), see Appendix D. The test revealed a significant difference between the two for COD, NVOC, Cl and TSS. Average recovery was 94% (COD), 102% (NVOC), 92% (Cl) and 94% (TSS). The difference could be attributed to influence from laboratories using methods other than those prescribed by the Danish EPA or methods previously shown to give deviation results (method 52 for Cl). The test was repeated after exclusion of the results for the non-approved methods and now showed no significant difference with the exception of TSS. Furthermore, the results of control measurements at Eurofins confirmed the assigned value for all parameters (Appendix E). The assigned values are therefore kept unchanged.

The difference between assigned value and average for TSS is attributed to difficulties for some laboratories to homogenise the samples. This is illustrated by the plot in Figure 1.

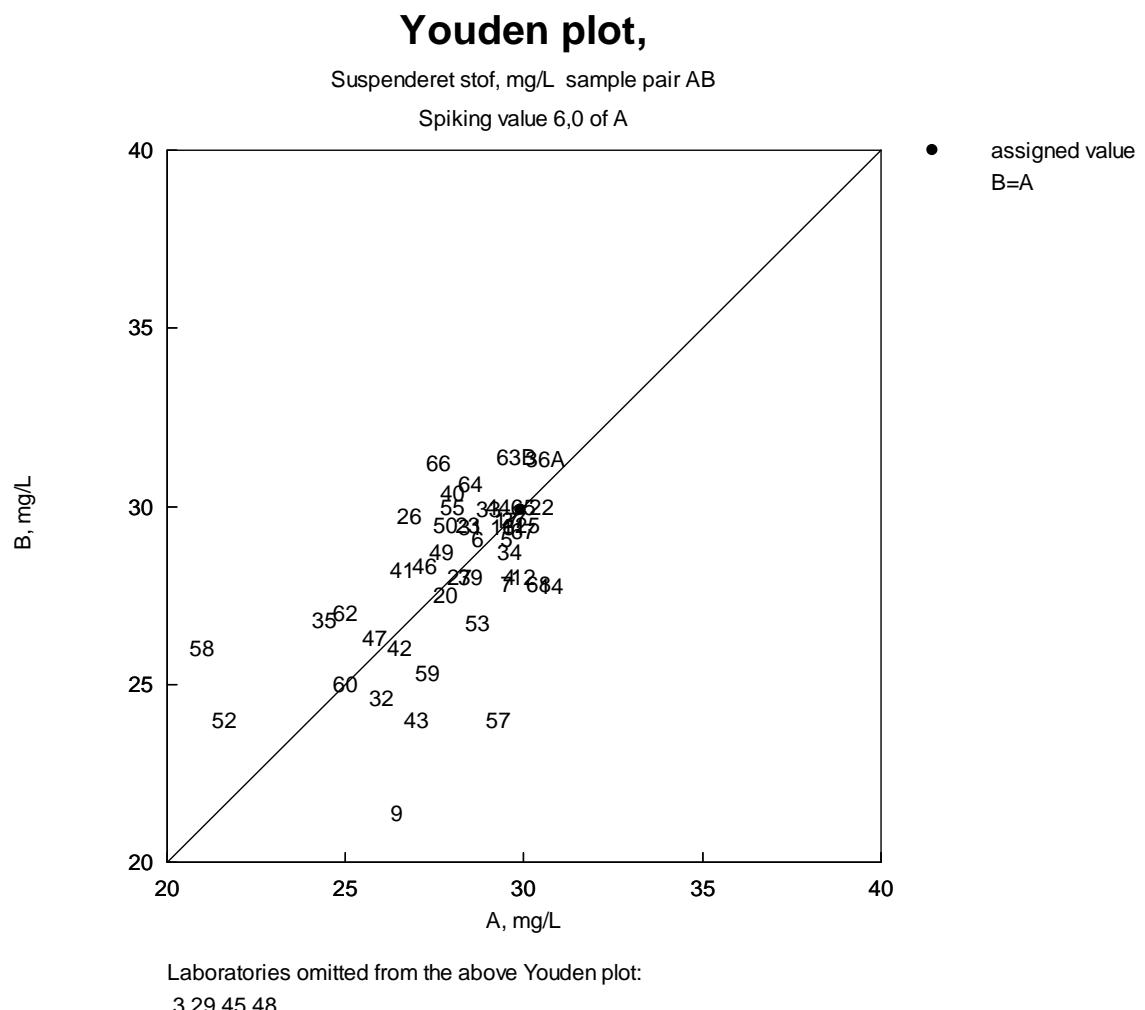

Figure 1 Youden plot for total suspended solids (TSS)

The plot shows a concentration of results around the assigned value and scattered results below the assigned value. The assigned value for TSS is therefore also kept unchanged.

The test of recovery of the assigned value was not performed for BOD_5 (w ATU) since this value is indicative and based upon data from only four participants.

3. HOMOGENEITY AND STABILITY OF SAMPLES

The homogeneity and stability of samples were tested using the following parameters as indicators:

TP	Homogeneity test
TSS	Combined homogeneity and stability test

The results of control measurements are shown in Appendix F. The appendix also gives the results of the statistical evaluation of the control data. The data are analysed by analysis of variance (ANOVA) giving:

1. the standard deviation/variance for replicates (the contribution from analytical variability),
2. the between bottle standard deviation/variance (the contribution from heterogeneity) and
3. the between days concentration difference (the contribution from instability).

Homogeneity is evaluated by comparing the between bottle variance to $0.3 * \text{the standard deviation}$ for evaluation of participants' performance ($0.3 \cdot \sigma$) specified by the Danish EPA /5/, whereas the stability is evaluated by comparing the concentration change of the samples to $0.3 \cdot \sigma$. This test ensures that heterogeneity and instability will not have negative influence on the evaluation of participant performance /6/.

The appendix also shows the standard deviation within and between laboratories from the proficiency test to allow comparison between tests performed and average quality from participating laboratories.

The tests for stability and homogeneity show that the samples are stable and homogeneous.

4. CONCLUSION

The quality control performed, including test of sample stability and homogeneity as well as test of recovery of spike and assigned values, shows that the samples and their assigned values are suitable for testing the proficiency of the participating laboratories for all parameters. The results are also suitable for estimation of the general quality of analyses among all participating laboratories.

For TP the participants could not recover the spike value. The difference between the calculated spike value and that found by the participants is small and the influence on evaluation of participant performance or estimation of general quality of analyses is insignificant.

For COD, NVOC, CI and TSS the participants did not recover the assigned value. Eu-rofins' scrutiny of the combined evidence gave the conclusion that the assigned value is correct. The assigned value is therefore kept unchanged and it is recommended as the basis for evaluation of participating laboratories.

t = $\sqrt{p} \cdot (d/s)$	2.6876
Sign. level, p(t)	0.0092 **

* denotes that there is a significant difference (t-test, 5%-level)

** denotes that there is a significant difference (t-test, 1%-level)

*** denotes that there is a significant difference (t-test, 0.1%-level)

UC denotes a Cochran outlier

Difference for sample pair AB is significantly different from 0,
 and data should be corrected with the difference (in spike value),
 during execution of Cochran's test.

Chloride, mg/L
Control of differences within sample pairs
